PROJECT REPORT / SOCIAL POST KIT

CampusDrop

Smart Lost & Found Management System

PROJECT SUMMARY

CampusDrop is an academic Java mini-project for organizing lost-and-found reporting and recovery on a college campus. It combines a browser dashboard, Java data structures, and an Oracle SQL persistence layer, with in-memory demo mode available when Oracle is not connected.

GitHub repository description

COPY AND PASTE

CampusDrop is a Java-based campus lost-and-found system featuring a web dashboard, possible item matching, FIFO claim handling, recovery history, and Oracle SQL persistence with an in-memory demo fallback.

The problem

Campus lost-and-found reports can be spread across paper registers, notice boards, and informal messages. This makes records harder to search, possible lost/found matches harder to spot, and claim handling harder to track consistently.

The solution

CampusDrop brings the workflow into one application: report an item, search existing records, review possible matches, submit and process claims, then record a successful return in recovery history.

Core capabilities

- Report lost and found items and search records by item ID, name, category, or location.
- Suggest possible matches using item names together with category or location.
- Submit claims and process them in first-in, first-out order.
- Track item status, view recovery history, and review dashboard statistics.
- Use a Stack for last-in, first-out action tracking.

Technology and data structures

COMPONENT	ROLE IN CAMPUSDROP
Java + Collections	Application logic and in-memory item, claim, and history workflows.
HashMap	Stores item records by ID for average constant-time ID lookup.
Queue / LinkedList / Stack	FIFO claim processing, recovery history, and LIFO action tracking.
Java HTTP server + web UI	Serves the dashboard and project workflow endpoints locally.
Oracle SQL + JDBC DAOs	Persists items, claims, and recovery records when the local database is configured and available.

Current scope

The project is configured for local use and can demonstrate its workflows with in-memory data if the Oracle connection is unavailable. Future improvements include stronger claim verification, fully reversible undo behavior, and hosted deployment.

READY TO COPY

LinkedIn post

A project introduction written for a general professional audience.

Introducing CampusDrop - a smarter way to manage lost and found items on campus.

Lost belongings are often reported through paper registers, notice boards, or scattered messages. That makes it difficult to search records, connect lost reports with found items, and keep track of claims.

I built **CampusDrop**, a Java-based system that brings these steps together in one place. Students or staff can report lost and found items, search records, view possible matches, submit claims, and track items through return and recovery history.

The project also gave me a practical way to apply core data structures:

- **HashMap** for item records and fast lookup by ID
- **Queue** for processing claims in FIFO order
- **LinkedList** for recovery history
- **Stack** for LIFO action tracking

The application includes a web dashboard served by Java's built-in HTTP server and uses JDBC DAOs to connect to Oracle SQL for persistent records. It can also run in in-memory demo mode when a database connection is unavailable.

This project helped me connect Java, data structures, database access, and a web interface in one end-to-end application. My next steps are to strengthen claim verification, make undo operations fully reversible, and explore a hosted deployment.

I'd love to hear suggestions for improving the workflow or the matching experience.

Caption options

Choose one to pair with the project post or a screenshot.

1 | SHORT AND PROFESSIONAL

Built CampusDrop, a Java-based campus lost-and-found system using HashMap, Queue, LinkedList, Stack, a web dashboard, and Oracle SQL persistence. A hands-on project in connecting data structures to a practical campus workflow.

2 | PROBLEM AND SOLUTION

From scattered lost-and-found reports to one organized workflow: CampusDrop helps record items, surface possible matches, manage claims, and track recoveries.

3 | TECHNICAL FOCUS

Putting Java data structures to work: HashMap for item lookup, Queue for FIFO claims, LinkedList for recovery history, and Stack for action tracking - all in my CampusDrop project.

4 | PERSONAL LEARNING

One project, several layers of learning: Java, data structures, JDBC, Oracle SQL, and a browser-based dashboard. Sharing CampusDrop, my smart lost-and-found mini-project.

Optional screenshot captions

- **Dashboard:** CampusDrop dashboard for browsing items, checking possible matches, and viewing campus recovery activity.
- **Workflow:** The item journey in CampusDrop: report, match, claim, process, and record the return.
- **Architecture:** Java collections handle runtime workflows, while JDBC DAOs connect CampusDrop to Oracle SQL persistence.

Before posting

- Replace the repository/demo link placeholder with a public link, or remove that line.
- Add a dashboard screenshot or short demo clip if available.
- Add your name, teammates, course, or institution only if you want them included.
- Keep database credentials and private student information out of screenshots.
